In the past, field effect transistors have been formed upon silicon substrates with considerable success. However, the use of silicon in such circuits has been largely supplanted by other materials including gallium arsenide and even gallium phosphide. One reason for this is that silicon and its alloys are relatively more difficult to fabricate than other materials. Gallium arsenide for example is much easier to fabricate than silicon, but has a much lower electron mobility than silicon. Accordingly, gallium arsenide transistors have operated at significantly higher speeds than silicon transistor but are far less efficient than silicon transistors in the conversion of electric energy to electrical energy. Thus, gallium arsenide transistors and other materials such as silicon alloys having improved mobility have been developed. Unfortunately however, it is necessary to make certain the increased mobility to adequate mobility to achieve satisfactory performance in the transistors. Much of the problem associated with silicon and its alloys is that they are difficult to find a suitable material to serve as electrodes for such circuits. Such electrodes must be ohmic, highly conductive and stable over a fairly wide range of operating conditions. Silicon-based semiconductors have not met all these conditions because of the difficulty in finding a suitable material to serve as the electrodes. Part of the problem in using silicon is that it is naturally a semiconductor material. While this is a
