=====
===== In this section, we consider the [*stability*]{} of the system in the frequency domain. We first discuss the impulse response in frequency domain. We notice that the impulse response of the system defined by

Eq. (1) is the Fourier transform of the time domain impulse response defined by Eq. (2). Therefore, the frequency response of the system can be calculated by applying the Fourier transform to Eq. (2) as follows:

$$\begin{aligned}
 H(f) &= \frac{1}{\pi} \int_{-\infty}^{\infty} H(t) e^{j2\pi ft} dt \\
 &= \frac{1}{\pi} \int_{-\infty}^{\infty} H_S(t) H_Z(t) e^{j2\pi ft} dt \\
 &= \frac{1}{\pi} \int_{-\infty}^{\infty} H_S(t) e^{j2\pi ft} \left[e^{j2\pi \sigma_z t} \right. \\
 &\quad \left. \left(\frac{\sigma_y^2}{\sigma_z^2 + \sigma_y^2} + 1 \right) \right] dt \\
 &= \frac{1}{\pi} \int_{-\infty}^{\infty} H_S(t) e^{j2\pi ft} e^{-\sigma_z^2 t^2 / 2} \left(\frac{\sigma_y^2}{\sigma_z^2 + \sigma_y^2} + 1 \right) dt
 \end{aligned}$$

Hd. Crystal structure of the PP2A regulatory subunit in a complex with okadaic acid and a fluorescence-based method to study ternary complex formation. The structures of the R2 and R4 regulatory subunits of the serine/threonine phosphatase 2A (PP2A) system have been elucidated previously. We determined the crystal structure of the heterodimer between the PP2A regulatory subunits R2 and R4 with a bound inhibitor from the diterpene okadaic acid (OA). A Ca(2+)-dependent complex between the C-terminal domain of R4 and an OA tetrahedral intermediate was used as a unique, primary probe to locate the OA anion at the PP2A interface. In addition, we used a fluorescence-based assay to monitor ternary complex formation between the R4 C-terminal domain, the hFip31 spindle-pole targeting protein, and PP2A in the absence of the R2 subunit. The results show that the complex is inhibited by OA and Ca(2+). No tertiary interactions were observed between R4 and hFip31 that could

explain the difference in inhibition between the N- and C-terminal domains of R4. The Ca(2+)-dependent complex is unique in that it is destabilized by OA and Ca(2+) due to the unique allosteric coupling of OA binding to the C-terminal peptide at the heterodimer interface.

Atherosclerosis in New Zealand: A 26 year perspective. To describe the geographic patterns of atherosclerosis in the New Zealand population. The data came from both the New Zealand Cardiovascular Disease Risk Factor Survey (NZCDRFS) of 1977 to 1988, and the 2000 to 2002 National Health Survey (NHS). During the 26 years between these surveys, the prevalence of risk factors such as hypertension, smoking, obesity, and hypercholesterolemia declined, while the prevalence of heart disease, angina, and myocardial infarction increased. CVD risk factors such as obesity, hypertension, and hypercholesterolemia occurred at a higher frequency in the most urbanised and youngest
