I want to compare a boolean property on a'master' model with the boolean property of a given instance of that same model. I can do the following: master = someModel.objects.get(pk=1) if master.active: do something What is the best way to express this in terms of a state (i.e. without writing if master.active)? A: There's no need to convert between the two. You can just test two instances of the same model (any model really, not just booleans): active = someModel.objects.get(pk=1) inactive = someModel.objects.get(pk=2) if active.active: do something Robustness in the appearance of complex systems. We consider a model of nonlinear coupled oscillators, whose appearance at the onset of a macroscopic system is studied. The model is linearized about its fixpoint solution and analyzed in the limit of nonlinear coupling. Applying the tools of perturbation theory, we find that the onset of the macroscopic response is exponentially suppressed by the smallness of the coupling. We derive analytically the critical response and deduce that the critical degree of amplitude frustration is determined by the coupling matrix. Our results are supported by numerical simulations.Q: How to render a countdown in Angular? I'm trying to replicate an effect I saw in a website, here is the actual scenario: On hovering, an animation will begin to countdown, after 1 second, it will change to the normal state. And here is the code I have so far for that: HTML CSS .timer { display 79a2804d6b
